Weather Tips

Hail is a form of solid precipitation, which consists of balls, or irregular lumps of ice that are individually called hail stones.

Hailstones consist mostly of water ice and measure between 0.20 inches and 5.9 inches in diameter; Hail is possible with most thunderstorms as it is produced by thunderclouds, usually at the leading edge of a severe storm system. Hail formation requires environments of strong, upward motion of air with the parent thunderstorm (similar to tornadoes) and lowered heights of the freezing level. Hail is most frequently formed in the interior of continents within the mid-latitudes of Earth, with hail generally confined to higher elevations within the tropics.

Hail can cause serious damage, notably to automobiles, aircraft, skylights, glass-roofed structures, livestock, and most commonly, farmers' crops. It is hardest to recognize hail damage on shingled roofs and flat roofs, but all roofs have their own hail damage detection problems. Make sure to have your roof checked out for damages after a hailstorm.
